Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$$< 1.0 \times 10^{-15} \text{ cm}^{-2}\text{sr}^{-1}\text{s}^{-1} \quad \text{for } 1.1 \times 10^{-4} < \beta < 0.1$$

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model.

Assumptions include: 1) $\tilde{\chi}_1^0$ (or $\tilde{\gamma}$) is lightest supersymmetric particle; 2) R -parity is conserved; 3) With the exception of \tilde{t} and \tilde{b} , all scalar quarks are assumed to be degenerate in mass and $m_{\tilde{q}_R} = m_{\tilde{q}_L}$. 4) Limits for sleptons refer to the $\tilde{\ell}_R$ states.

See the Particle Listings for a Note giving details of supersymmetry.

Mass $m > 82.3 \text{ GeV}$, CL = 95% [$m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 3 \text{ GeV}$]

$\tilde{\tau}$ — scalar tau (stau)

Mass $m > 81.0 \text{ GeV}$, CL = 95% [$m_{\tilde{\tau}_R} - m_{\tilde{\chi}_1^0} > 8 \text{ GeV}$]

\tilde{q} — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.

Mass $m > 250 \text{ GeV}$, CL = 95% [$\tan\beta = 2$, $\mu < 0$, $A = 0$]

\tilde{b} — scalar bottom (sbottom)

Mass m none 40–75 GeV, CL = 95%

[$\tilde{b} \rightarrow b\tilde{\chi}_1^0$, all θ_b , $m_{\tilde{b}} - m_{\tilde{\chi}_1^0} > 10 \text{ GeV}$]

\tilde{t} — scalar top (stop)

Mass $m > 86.4 \text{ GeV}$, CL = 95%

[$\tilde{t} \rightarrow t\tilde{\chi}_1^0$, all θ_t , $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > 5 \text{ GeV}$]

\tilde{g} — gluino

There is some controversy on whether gluinos in a low-mass window ($1 \lesssim m_{\tilde{g}} \lesssim 5 \text{ GeV}$) are excluded or not. See the Supersymmetry Listings for details.

The limits summarised here refer to the high-mass region ($m_{\tilde{g}} \gtrsim 5 \text{ GeV}$), and include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$.

The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling,

Mass $m > 190 \text{ GeV}$, CL = 95% [$\tan\beta = 2$, $\mu < 0$, $A = 0$]

Mass $m > 260 \text{ GeV}$, CL = 95% [$m_{\tilde{q}} = m_{\tilde{g}}$, $\tan\beta = 2$, $\mu < 0$, $A = 0$]

Technicolor

Searches for a color-octet techni- ρ constrain its mass to be greater than 260 to 480 GeV, depending on allowed decay channels. Similar bounds exist on the color-octet techni- ω .

Scale Limits Λ for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L$$

Excited Leptons

The limits from $\ell^{*+} \ell^{*-}$ do not depend on λ (where λ is the $\ell \ell^*$ transition coupling). The λ -dependent limits assume chiral coupling, except for the third limit for e^* which is for nonchiral coupling. For chiral coupling, this limit corresponds to $\lambda_\gamma = \sqrt{2}$.
