A REVIEW GOES HERE – Check our WWW List of Reviews

## Half-life Measurements and Limits for Double- $\beta$ Decay

In all cases of double-beta decay,  $(Z,A) \rightarrow (Z+2,A) + 2e^- + (0 \text{ or } 2)\bar{\nu}_e$ . In the following Listings, only best or comparable limits or lifetimes for each isotope are reported. For  $2\nu$  decay, which is well established, only measured half-lives are reported.

- <sup>1</sup> DANEVICH 01 place limit on  $0\nu$  decay of  $^{160}\text{Gd}$  using  $\text{Gd}_2\text{SiO}_5:\text{Ce}$  crystal scintillators. The limit is more stringent than KOBAYASHI 95.
- <sup>2</sup> DANEVICH 01 place limits on  $0\nu$  decay of  $^{160}\text{Gd}$  into excited  $2^+$  state of daughter nucleus using  $\text{Gd}_2\text{SiO}_5:\text{Ce}$  crystal scintillators.
- <sup>3</sup> ALESSANDRELLO 00 limit is based on calorimetric measurement with an array of 20  $\text{TeO}_2$  cryogenic detectors. Uses enriched and natural Te crystals. Replaces ALESSANDRELLO 98.
- <sup>4</sup> BRUDANIN 00 determine a limit for  $0\nu$  halflife of  $^{48}\text{Ca}$ . Their value is less accurate than YOU 91.
- <sup>5</sup> BRUDANIN 00 determine the  $2\nu$  halflife of  $^{48}\text{Ca}$ . Their value is less accurate than BALYSH 96.
- <sup>6</sup> DANEVICH 00 provides calorimetric measurement of  $2\nu$  decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Agrees with EJIRI 95 and ARNOLD 96.
- <sup>7</sup> DANEVICH 00 places limits on  $0\nu$  decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Replaces GEORGADZE 95.
- <sup>8</sup> DANEVICH 00 places limit on  $0\nu$  decay of  $^{116}\text{Cd}$  into first excited  $0^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators.
- <sup>9</sup> ARNOLD 99 measure directly the  $2\nu$  decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.
- <sup>10</sup> BAUDIS 99B is a continuation of the work of BAUDIS 97. The limit is based on a subset of data using a pulse shape event selection. The exposure time is 24.2 kg-yr. The more stringent limit, in parentheses, results from unphysical data (measured rate significantly below expected background), while the smaller value is the experimental sensitivity as defined by FELDMAN 98. This work supersedes BAUDIS 97 as the most stringent result. AVIGNONE 00 has expressed some concerns about the way the most stringent lifetime limit (given in parentheses) was determined.
- <sup>11</sup> LUESCHER 98 report a limit for the  $0\nu$  decay of  $^{136}\text{Xe}$  TPC. Supersedes VUILLEUMIER 93.
- <sup>12</sup> ALSTON-GARNJOST 97 report evidence for  $2\nu$  decay of  $^{100}\text{Mo}$ . This decay has been also observed by EJIRI 91, DASSIE 95, and DESILVA 97.
- <sup>13</sup> DESILVA 97 result for  $2\nu$  decay of  $^{100}\text{Mo}$  is in agreement with ALSTON-GARNJOST 97 and DASSIE 95. This measurement has the smallest errors.
- <sup>14</sup> DESILVA 97 result for  $2\nu$  decay of  $^{150}\text{Nd}$  is in marginal agreement with ARTEMEV 93. It has smaller errors.
- <sup>15</sup> DESILVA 97 do not explain whether their efficiency for  $0\nu$  decay of  $^{150}\text{Nd}$  was calculated under the assumption of a  $\langle m_\nu \rangle$ ,  $\langle \lambda \rangle$ , or  $\langle \eta \rangle$  driven decay.
- <sup>16</sup> GUENTHER 97 half-life for the  $2\nu$  decay of  $^{76}\text{Ge}$  is not in good agreement with the previous measurements of BALYSH 94, AVIGNONE 91, and MILEY 90.
- <sup>17</sup> ARNOLD 96 measure the  $2\nu$  decay of  $^{116}\text{Cd}$ . This result is in agreement with EJIRI 95, but has smaller errors. Supersedes ARNOLD 95.
- <sup>18</sup> BALYSH 96 measure the  $2\nu$  decay of  $^{48}\text{Ca}$ , using a passive source of enriched  $^{48}\text{Ca}$  in a TPC.

- <sup>19</sup> EJIRI 96 use energy and angular correlations of the 2  $\beta$ -rays in efficiency estimate to give limits for the  $0\nu$  decay modes associated with  $\langle m_\nu \rangle$ ,  $\langle \lambda \rangle$ , and  $\langle \eta \rangle$ , respectively. Enriched <sup>100</sup>Mo source is used in tracking calorimeter. These are the best limits for <sup>100</sup>Mo. Limit is more stringent than ALSTON-GARNJOST 97.
- <sup>20</sup> TAKAOKA 96 measure the geochemical half-life of <sup>130</sup>Te. Their value is in disagreement with the quoted values of BERNATOWICZ 92 and KIRSTEN 83; but agrees with several other unquoted determinations, e.g., MANUEL 91.
- <sup>21</sup> BARABASH 95 cannot distinguish  $0\nu$  and  $2\nu$ , but it is inferred indirectly that the  $0\nu$  mode accounts for less than 0.026% of their event sample. They also note that their result disagrees with the previous experiment by the NEMO group (BLUM 92).
- <sup>22</sup> BERNATOWICZ 92 finds <sup>128</sup>Te/<sup>130</sup>Te activity ratio from slope of <sup>128</sup>Xe/<sup>132</sup>Xe vs <sup>130</sup>Xe/<sup>132</sup>Xe ratios during extraction, and normalizes to lead-dated ages for the <sup>130</sup>Te lifetime. The authors state that their results imply that "(a) the double beta decay of <sup>128</sup>Te has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences... (b) Theoretical calculations ... underestimate the [long half-lives of <sup>128</sup>Te <sup>130</sup>Te] by 1 or 2 orders of magnitude, pointing to a real suppression in the  $2\nu$  decay rate of these isotopes. (c) Despite [this], most  $\beta\beta$ -models predict a *ratio* of  $2\nu$  decay widths ... in fair agreement with observation." Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray <sup>128</sup>Xe production corrections.
- <sup>23</sup> TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the <sup>238</sup>U transition in the same range as deduced for <sup>130</sup>Te and <sup>76</sup>Ge. On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.
- <sup>24</sup> KIRSTEN 83 reports " $2\sigma$ " error. References are given to earlier determinations of the <sup>130</sup>Te lifetime.

### $\langle m_\nu \rangle$ , The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- $\beta$ Decay

$\langle m_\nu \rangle = |\sum U_{1j}^2 m_{\nu_j}|$ , where the sum goes from 1 to  $n$  and where  $n$  = number of neutrino generations, and  $\nu_j$  is a Majorana neutrino. Note that  $U_{ej}^2$ , not  $|U_{ej}|^2$ , occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

- <sup>25</sup> ALESSANDRELLO 00 spread in limit for  $\langle m_\nu \rangle$  reflects the range found for theoretical matrix elements.
- <sup>26</sup> DANEVICH 00 limit for  $\langle m_\nu \rangle$  is based on the nuclear matrix elements of STAUDT 90 (2.6 eV) and ARNOLD 96 (2.4 eV).
- <sup>27</sup> ARNOLD 99 limit based on the nuclear matrix elements of STAUDT 90.
- <sup>28</sup> BAUDIS 99B derive a limit for  $\langle m_\nu \rangle$  using the matrix elements of STAUDT 90. For this most restrictive limit, the uncertainty we give for  $\langle m_\nu \rangle$  reflects estimated theoretical uncertainties in the matrix element calculations. The less restrictive limit is based on the quoted experimental sensitivity while the lower value in parentheses makes use of measured rates significantly below background. This is the most stringent bound on  $\langle m_\nu \rangle$ . It supersedes the limit of GUENTHER 97.
- <sup>29</sup> LUESCHER 98 limit for  $\langle m_\nu \rangle$  is based on the matrix elements of ENGEL 88.
- <sup>30</sup> ALSTON-GARNJOST 97 obtain the limit for  $\langle m_\nu \rangle$  using the matrix elements of ENGEL 88. The limit supersedes ALSTON-GARNJOST 93.
- <sup>31</sup> BAUDIS 97 limit for  $\langle m_\nu \rangle$  is based on the matrix elements of STAUDT 90.
- <sup>32</sup> EJIRI 96 obtain the limit for  $\langle m_\nu \rangle$  using the matrix elements of TOMODA 91.
- <sup>33</sup> DANEVICH 95 is identical to GEORGADZE 95.
- <sup>34</sup> BERNATOWICZ 92 finds these majorona neutrino mass limits assuming that the measured geochemical decay width is a limit on the  $0\nu$  decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.
- <sup>35</sup> ELLIOTT 92 uses the matrix elements of HAXTON 84.

### Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later.  $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$  and  $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$ , where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

$\langle \lambda \rangle$ ( $10^{-6}$ )	CL%	$\langle \eta \rangle$ ( $10^{-8}$ )	CL%	ISOTOPE	METHOD	DOCUMENT ID
● ● ● We do not use the following data for averages, fits, limits, etc. ● ● ●

- <sup>36</sup> ALESSANDRELLO 00 limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  use several nuclear matrix element calculations. Limits reported for  $\langle m_\nu \rangle = \langle \eta \rangle = \langle \lambda \rangle = 0$ .
- <sup>37</sup> DANEVICH 00 limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  are based on nuclear matrix element of STAUDT 90. Replaces DANEVICH 95.
- <sup>38</sup> GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.
- <sup>39</sup> EJIRI 96 obtain limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  using the matrix elements of TOMODA 91.
- <sup>40</sup> VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit  $2.6 \times 10^{23}$  y at 90%CL.
- <sup>41</sup> BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the  $0\nu$  width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on  $\eta$ . Further details of the experiment are given in BERNATOWICZ 93.
