c-QUARK MASS

The *c*-quark mass corresponds to the "running" mass $m_c\ (\mu = m_c)$ in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ scheme using two-loop QCD perturbation theory with $\alpha_s(\mu = m_c) = 0.39$. The range 1.0–1.4 GeV for the $\overline{\text{MS}}$ mass corresponds to 1.47–1.83 GeV for the pole mass (see the "Note on Quark Masses").

[1] KUHN 07 determine $\overline{m}_c(\mu = 3\ \text{GeV}) = 0.986 \pm 0.013$ GeV and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+ e^- \to$ hadrons in the charm threshold region.
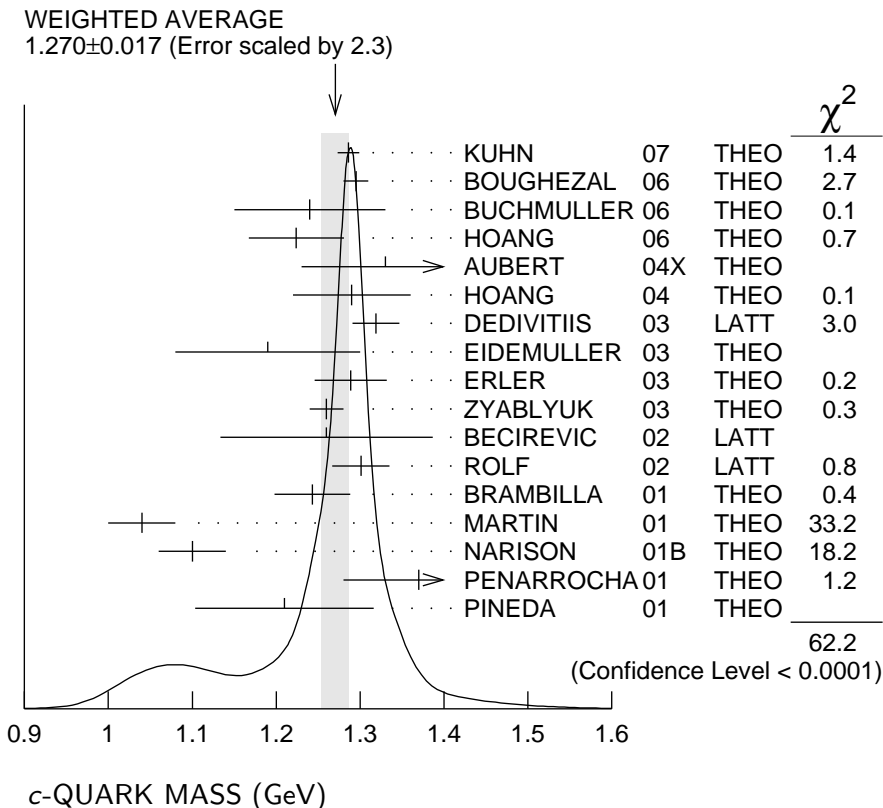

[2] BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order α_s^3.

[3] BUCHMULLER 06 determine m_b and m_c by a global fit to inclusive B decay spectra.

[4] HOANG 06 determines $\overline{m}_c(\overline{m}_c)$ from a global fit to inclusive B decay data. The B decay distributions were computed to order $\alpha_s^2 \beta_0$, and the conversion between different m_c mass schemes to order α_s^3.

[5] AUBERT 04X obtain m_c from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration.

[6] HOANG 04 determines $\overline{m}_c(\overline{m}_c)$ from moments at order α_s^2 of the charm production cross-section in e^+e^- annihilation.

[7] DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

[8] EIDEMULLER 03 determines m_b and m_c using QCD sum rules.

[9] ERLER 03 determines m_b and m_c using QCD sum rules. Includes recent BES data.

[10] ZYABLYUK 03 determines m_c by using QCD sum rules in the pseudoscalar channel and comparing with the η_c mass.

[11] BECIREVIC 02 uses Monte-Carlo calculations of lattice Ward identities and the D_s mass. The authors estimate an error of about 5% for use of the quenched approximation, not included in systematic error of 0.12.

[12] ROLF 02 determines m_c from a quenched lattice calculation of the D_s mass. The error estimate is for all systematics except the quenched approximation, including lattice spacing effects, finite volume effects, excited states contamination, rounding errors, and the scale uncertainty. The authors estimate the uncertainty due to the quenched approximation may be about 3%.

[13] BRAMBILLA 01 determine $\overline{m}_c(\overline{m}_c)$ from a computation of the J/ψ mass.

[14] MARTIN 01 obtain a pole mass of 1.33–1.4 GeV from an analysis of R, the rate for $e^+e^- \rightarrow$ hadrons. We have converted this to the $\overline{\text{MS}}$ scheme using the two-loop formula.

[15] NARISON 01B uses pseudoscalar sum rules in the B and D meson channels.

[16] PENARROCHA 01 result is from an analysis of the BES-II e^+e^- data using finite energy sum rules.

[17] PINEDA 01 uses the $\Upsilon(1S)$ system and the B-D mass difference to determine m_c. The errors are due to theory, and the uncertainty in λ_1 and m_b.

[18] EIDEMULLER 01 result is QCD sum rule analysis of charmonium using NRQCD at next-to-next-to-leading order.

[19] KUHN 01 uses an analysis of the e^+e^- total cross section to hadrons.

[20] Study of opposite sign dimuon events.

[21] VILAIN 99 obtain the charm quark mass from an analysis of charm production in neutrino scattering.
